Abstract

Diabetes is associated with microcirculatory dysfunction and heart failure and changes in insulin and IGF1 levels. Whether human cardiac microvascular endothelial cells (HMVEC-Cs) are sensitive to insulin and/or IGF1 is not known. We studied the role of insulin receptors (IRs) and IGF1 receptors (IGF1Rs) in metabolic, mitogenic and anti-inflammatory responses to insulin and IGF1 in HMVEC-Cs and human umbilical vein endothelial cells (HUVECs). IR and IGF1R gene expression was studied using real-time RT-PCR. Receptor protein expression and phosphorylation were determined by western blot and ELISA. Metabolic and mitogenic effects were measured as glucose accumulation and thymidine incorporation. An E-selectin ELISA was used to investigate inflammatory responses. According to gene expression and protein in HMVEC-Cs and HUVECs, IGF1R is more abundant than IR. Immunoprecipitation

with anti-IGF1R antibody and immunoblotting with anti-IR antibody and vice versa, showed insulin/IGF1 hybrid receptors in HMVEC-Cs. IGF1 at a concentration of 10^{-8} mol/l significantly stimulated phosphorylation of both IGF1R and IR in HMVEC-Cs. In HUVECs IGF1 10^{-8} mol/l phosphorylated IGF1R. IGF1 stimulated DNA synthesis at 10^{-8} mol/l and glucose accumulation at 10^{-7} mol/l in HMVEC-Cs. TNF- α dramatically increased E-selectin expression, but no inflammatory or anti-inflammatory effects of insulin, IGF1 or high glucose were seen. We conclude that HMVEC-Cs express more IGF1Rs than IRs, and mainly react to IGF1 due to the predominance of IGF1Rs and insulin/IGF1 hybrid receptors. TNF- α has a pronounced pro-inflammatory effect in HMVEC-Cs, which is not counteracted by insulin or IGF1.

Journal of Endocrinology (2012) **215**, 89–96

Introduction

The effects of diabetes on the microcirculation manifest as diabetic microangiopathy and on the macrocirculation as atherosclerosis and media sclerosis. The development of these complications is dependent on the integrity and function of the endothelium (Kim *et al.* 2006, Pambianco *et al.* 2006). There is a strong association between microvascular complications and cardiomyopathy leading to heart failure (Tarquini *et al.* 2010). Alterations in the insulin-like growth factor (IGF) system have been demonstrated in diabetic patients when compared with healthy individuals (Bereket *et al.* 1999, Delafontaine *et al.* 2004, Hedman *et al.* 2004).

Diabetes and insulin resistance are associated with inflammation. It has been suggested that the high levels of TNF- α expressed during inflammation is a link between insulin resistance and coronary microvascular dysfunction, as TNF- α has been shown to affect superoxide production and NO bioactivity (Picchi *et al.* 2010). Furthermore, insulin has been shown to have anti-inflammatory effects, suppressing adhesion molecules and NF- κ B (Dandona *et al.* 2009).

Insulin and IGF1 mediate their effects by binding to their cognate cell surface receptors: the insulin receptor (IR) and the IGF1 receptor (IGF1R). The receptors are highly homologous and originate from the same family of tyrosine kinase receptors (Siddle *et al.* 2001). They both consist of two $\alpha\beta$ -dimers where the α -subunit is the ligand-binding extracellular part and the β -subunit, containing the tyrosine kinase domain, is the transmembrane part (Siddle *et al.* 2001). Insulin and IGF1 cross-react with each other's receptor but with 100- to 1000-fold lower affinity than to their own receptor (Werner *et al.* 2008).

Stoichiometric assembly of the IR and IGF1R $\alpha\beta$ -dimers results in the formation of an insulin/IGF1 hybrid receptor with one $\alpha\beta$ -dimer from each original receptor (Moxham *et al.* 1989). Hybrid receptors have been shown to have a binding affinity similar to that of the IGF1R, i.e. they bind IGF1 with high affinity, but not insulin (Soos *et al.* 1993, Slaaby *et al.* 2006). We have reported that IRs and IGF1Rs form insulin/IGF1 hybrid receptors in human macro- and microvascular endothelial cells (Nitert *et al.* 2005, Chisalita *et al.* 2006, Johansson *et al.* 2008), which could be of importance for insulin sensitivity.

Endothelial cells from different locations show a range of heterogeneity with respect to appearance, phenotype, protein expression and intracellular enzymes (Cines *et al.* 1998). In human diabetic myocardium, endothelial swelling and thickening of the capillary basement membrane occur (Asghar *et al.* 2009). Human microvascular endothelial cells (HMVECs) are sensitive to IGF1s but insensitive to insulin, and IGF1Rs are several times more abundant on these cells than IRs (Chisalita & Arnqvist 2004). Whether human microvascular endothelial cells-cardiac (HMVEC-Cs) are sensitive to insulin and/or IGF1 is not known. Our aim was therefore to study the role of IRs and IGF1Rs in metabolic, mitogenic and anti-inflammatory responses to insulin and IGF1 in HMVEC-Cs. For comparison, human umbilical vein endothelial cells (HUVECs) were also investigated.

Materials and Methods

Cells and culture

Cell culture flasks and plates were purchased from Corning (Schiphol-Rijk, The Netherlands) and all other cell culture materials were purchased from Invitrogen or as indicated in the text.

Human cardiac microvascular endothelial cells

Primary cultures of HMVEC-Cs from different batches were purchased from Lonza (Basel, Switzerland). The cells stained positive for acetylated LDL and von Willebrand's (Factor VIII) antigen but did not stain for smooth muscle α -actin. They were cultured in EGM-2MV (Microvascular endothelial growth medium-2) (Lonza) in 75 cm² culture flasks until near confluent. Medium was changed two to three times a week and cells were passaged using trypsin (Lonza) when near confluent. Cells used in experiments were from passages three to nine.

Human umbilical vein endothelial cells

HUVECs were isolated from umbilical cords provided by the Department of Obstetrics, Linköping University Hospital, Linköping, Sweden. The umbilical cords were collected in sterile PBS containing penicillin (100 IU/ml) and streptomycin (100 µg/ml) at 4 °C. The umbilical cord vein was washed with PBS and then incubated with 0.5 mg/ml collagenase type 1 (Sigma-Aldrich) in DMEM containing 25 mmol/l HEPES, 10 IU/ml penicillin and 10 µg/ml streptomycin for 15 min at 37 °C. The collagenase solution containing the endothelial cells was collected in DMEM containing 10 IU/ml penicillin and 10 µg/ml streptomycin, and the vein was then washed with PBS to collect any remaining cells. The cell suspension was centrifuged twice at 500 *g* for 5 min and washed in between with HUVEC culture medium (DMEM supplemented with 8% (v/v) foetal bovine serum,

100 IU/ml penicillin, 100 µg/ml streptomycin, 2 µg/ml Fungizone and EGM-2 SingleQuot kit (Lonza) (0.04% (v/v) hydrocortisone, 0.4% (v/v) human fibroblast growth factor, 0.1% (v/v) vascular endothelial growth factor, 0.1% (v/v) R³-IGF1, 0.1% (v/v) ascorbic acid, 0.1% (v/v) human epithelial growth factor, 0.1% (v/v) gentamycin-amphotericin). The cells were cultured in 75 cm² flasks coated with 0.2% (w/v) gelatin in HUVEC culture medium. The medium was changed two to three times a week and cells were passaged using trypsin when near confluent. Cells used in experiments were from passages one to three.

Real-time RT-PCR

RNA was extracted using E.Z.N.A. Total RNA kit (Omega Bio-tek, Doraville, GA, USA) according to the manufacturer's instructions. Cells were lysed directly in the flasks and RNA samples were stored at -70 °C until further use. One microgram of RNA was transcribed to cDNA using SuperScript II Reverse Transcriptase, purchased from Invitrogen. cDNA was stored at -20 °C until further use.

Comparative quantitative real-time PCR was performed using primers and probes for IR, IGF1R and GLUT4, purchased from Scandinavian Gene Synthesis (Köping, Sweden; Bäck & Arnqvist 2009). Twenty to one hundred nanogram cDNA was mixed with 300 nmol/l sense and antisense primers, 50 nmol/l probe, 12.5 µl 2× TaqMan Fast Universal PCR Master Mix (Applied Biosystems) and water to a final volume of 25 µl. DNA amplification was run and measured in an ABI Prism 7500 Fast Sequence Detector System (Applied Biosystems). Data were analysed using the ΔC_t method described by Applied Biosystems Bulletin #2. Pre-developed TaqMan assay reagent GAPDH, purchased from Applied Biosystems, was used for normalisation.

Receptor ELISA

Near confluent HMVEC-Cs or HUVECs were serum-deprived overnight in low glucose (5.6 mmol/l) DMEM containing 0.1% glucose, 100 IU/ml penicillin, 100 µg/ml streptomycin, 2 µg/ml Fungizone and 0.1% (w/v) BSA. Insulin or IGF1 at indicated concentrations were added to the flasks and they were incubated at 37 °C for 10 min. The cells were then washed twice with cold PBS and collected in cold PBS. The suspension was centrifuged at 700 *g* and 4 °C for 5 min. The pellet was dissolved in lysis buffer (pH 7.5) containing 20 mmol/l TrizmaBase, 150 mmol/l NaCl, 5 mmol/l EDTA, 0.5% (w/v) sodium deoxycholate and 0.5% (v/v) Triton X-100 with the addition of 1 mmol/l phenylmethylsulphonyl fluoride (PMSF), 1.5 µg/ml leupeptin, 1 mmol/l Na₃VO₄ and 1.5 µg/ml aprotinin before use. The cells were lysed on ice for 30 min and then centrifuged at 12 000 *g* and 4 °C for 10 min. The supernatant was stored at -70 °C until further use. Human total IR, total IGF1R, phospho-IR or phospho-IGF1R were measured using DuoSet IC kits from R&D Systems

(Minneapolis, MN, USA) and analyses were performed according to the manufacturer's instructions. Total protein was measured using BCA Protein Assay Kit (Pierce, Rockford, IL, USA) according to the manufacturer's instructions.

Immunoprecipitation, SDS-PAGE and western blot

HMVEC-Cs were serum-deprived overnight in DMEM containing 100 IU/ml penicillin, 100 µg/ml streptomycin, 2 µg/ml Fungizone and 0.1% (w/v) BSA. Insulin or IGF1 at indicated concentrations were added to the flasks and incubated at 37 °C for 10 min. The medium was then removed and lysis buffer (pH 7.5) containing 20 mmol/l TrizmaBase, 150 mmol/l NaCl, 5 mmol/l EDTA, 0.5% (w/v) sodium deoxycholate and 0.5% (v/v) Triton X-100 with addition of 1 mmol/l PMSF, 1.5 µg/ml leupeptin, 1 mmol/l Na₃VO₄ and 1.5 µg/ml aprotinin was added to the flasks. The cells were lysed on ice for 30 min and then harvested by scraping. The lysate was centrifuged at 12 000 g for 15 min at 4 °C and the supernatant was stored at -70 °C until further use.

HMVEC-C lysates were immunoprecipitated (IP) with either rabbit polyclonal anti-IR β antibody (c-19) or rabbit polyclonal anti-IGF1R β antibody (c-20) (Santa Cruz Biotechnology), diluted 1:400 and incubated at 4 °C for 2 h. Twenty milligrams per milliliter Protein A Sepharose (GE Healthcare Bio-Sciences AB, Uppsala, Sweden) in 0.1% (w/v) BSA was then added and the lysates were incubated overnight at 4 °C with gentle rocking. The next day lysates were centrifuged at 6500 g for 5 min, supernatants were removed and pellets were washed three times with the lysis buffer. Pellets were then dissolved in SDS-PAGE sample buffer (6.25 mmol/l TrizmaBase, 1% (w/v) SDS, 10% (v/v) glycerol, 0.001% (v/v) bromophenol) with addition of 2% (v/v) β-mercaptoethanol and boiled for 3 min.

IP proteins were separated in 7.5% acrylamide gels and then electrophoretically blotted to polyvinylidene difluoride membranes. After blocking in 3% (w/v) BSA, membranes were incubated with antiphosphotyrosine (PY20) or, after stripping membranes in 62 mmol/l Tris-HCl, 2% (w/v) sodium dodecylsulphate, and 100 mmol/l β-mercaptoethanol for 30 min at 56 °C, with anti-IGF1R (c-20) or anti-IR (c-19) antibodies. Bound antibodies were detected using HRP-conjugated secondary antibodies and the ECL-plus kit from GE Healthcare.

Thymidine incorporation

HMVEC-Cs, around 100 000 cells/well, were plated in six-well plates and grown until near confluence. The cells were incubated with insulin or IGF1 at indicated concentrations in serum-free, low glucose DMEM overnight and then with 1 µCi/ml [6-³H]thymidine for 3 h at 37 °C, 5% CO₂. Cells were washed and DNA was then precipitated in ice cold 5% (w/v) trichloroacetic acid for 15 min at 4 °C. After treatment with 0.1 mol/l potassium hydroxide for 1–2 h at room temperature, the lysate was added to UltimaGold

scintillation fluid (Chemical Instruments AB (CiAB), Sollentuna, Sweden) and the radioactivity was measured. Data were expressed as percent of radioactivity in untreated control cells. VEGF-165 (R&D Systems) was used as a positive control.

Glucose accumulation

HMVEC-Cs, around 100 000 cells/well, were plated in six-well plates and grown until near confluence. The cells were serum-deprived overnight and then incubated for 3 h in serum-free, low glucose DMEM with addition of 0.2 µCi/ml D-[U-¹⁴C]glucose and insulin or IGF1 at indicated concentrations. The wells were then washed and cells were lysed in 0.1% (w/v) sodium dodecylsulphate. The lysate was added to UltimaGold scintillation fluid (CiAB) and the radioactivity was measured. Data were expressed as percent of radioactivity in unstimulated control cells. VEGF-165 (R&D Systems) was used as a positive control.

E-selectin ELISA

Expression of E-selectin was detected using an ELISA as described by Strindhall *et al.* (1997). Briefly, HUVECs or HMVEC-Cs, 10 000 cells/well, were seeded in a 96-well microplate and incubated for 2 days. They were then stimulated for 4 h with glucose, TNF-α, IL6, IGF1 or insulin at indicated concentrations. The cells were fixed with formalin and incubated with anti-E-selectin antibody for 1 h. Secondary antibody was added and the plate was incubated for 1 h. The substrate used was *p*-nitrophenyl-phosphate in diethanolamine. Optical densities were measured at 405 nm every 15 min for 1 h.

Statistical analysis

Statistical comparisons were made with SPSS 17.0 (SPSS, Inc. Headquarters, Chicago, IL, USA) by ANOVA. For *post hoc* analysis Dunnett's test was used. When indicated, a non-parametric test, related-samples Wilcoxon signed-ranks test, was used. A *P* value <0.05 was considered statistically significant. Data are presented as mean ± S.E.M. or as median and the interquartile range (25th and 75th percentiles).

Results

Gene expression

The gene expression of IGF1R and IR was measured in HMVEC-Cs (Fig. 1A) and HUVECs (Fig. 1B). Results were calculated as the ratio of IGF1R to IR gene expression where IR expression was converted to one. The results are given as median and the interquartile range (25th and 75th percentiles). In HMVEC-Cs the IGF1R was 120.3 (112.6–173.6) times more abundant than the IR, and in HUVECs the IGF1R was 19.9 (14.7–22.3) times more

Figure 1 Gene expression of IR and IGF1R in HMVEC-Cs and HUVECs. Relative gene expression of IGF1R to IR in (A) HMVEC-Cs ($n=5$) and (B) HUVECs ($n=10$). IR is converted to 1, data are fold expressions of IGF1R relative to IR, shown as median and the interquartile range (25th and 75th percentiles). * $P<0.05$ when results were compared with related-samples Wilcoxon signed-ranks test.

abundant. The IGF1R/IR ratio was significantly higher in HMVEC-Cs than in HUVECs ($P<0.05$).

The median Ct values in HMVEC-Cs were 24.9 for IGF1R expression, 31.9 for IR expression and 15.2 for GAPDH expression. In HUVECs the median Ct values were 26.8 for IGF1R expression, 30.5 for IR expression and 21.4 for GAPDH expression.

We measured the gene expression of IGF1Rs and IRs in freshly isolated or cultured HUVECs to see if our culturing conditions altered receptor expression. No differences were found in the ratio of IGF1R to IR gene expression between cultured (19.9 (14.7–22.3)) and freshly isolated (21.4 (16.9–25.6)) cells. There was no expression of GLUT4 in HUVECs or HMVEC-Cs (data not shown).

IR and IGF1R protein expression

In HMVEC-Cs we detected IR and IGF1R protein by western blot (Fig. 2). When immunoprecipitating lysates with anti-IGF1R antibody and immunoblotting with anti-IR antibody, we discovered bands on the gel and vice versa, suggesting there were hybrid receptors present on these cells.

With ELISA we could quantify the amounts of IGF1R. In HMVEC-Cs we found 2.77 ± 0.20 pg IGF1R/ μ g total protein. The same amounts were detected in HUVECs (2.86 ± 0.18 pg IGF1R/ μ g total protein). The IGF1R assay (detection range 250–16 000 pg/l) was several times more sensitive than the IR assay (detection range 1250–80 000 pg/l), making it difficult to quantify IR in HMVEC-Cs or HUVECs as the levels in our study were below the detection range of the kit.

Receptor phosphorylation with ELISA

The amount of phosphorylated receptor protein on HMVEC-Cs (Fig. 3A) and HUVECs (Fig. 3B) was examined using phospho-specific ELISAs against IGF1R or IR. Cells were stimulated with insulin or IGF1 at 10^{-8} mol/l and then lysed. Data were expressed as percent of unstimulated control. In HUVECs there was a significant difference between unstimulated control and IGF1 10^{-8} mol/l stimulated cells regarding IGF1R phosphorylation. In HMVEC-Cs IGF1 10^{-8} mol/l stimulated phosphorylation of both IGF1R and IR; insulin had no effect on receptor phosphorylation in either cell type.

Figure 2 Abundance and phosphorylation of IGF1R and IR in HMVEC-Cs. Cell lysate was IP with polyclonal antibodies against either IGF1R β -subunit (c-20) (A) or the IR β -subunit (c-19) (B). Immunoblotting with a phosphotyrosine antibody (PY-20) was used to analyse phosphorylation. Results shown in the blots represent four different experiments.

Figure 3 Phospho-ELISA in HMVEC-Cs and HUVECs. The amounts of phosphorylated IGF1R (black bars) or IR (white bars) were measured in (A) HMVEC-Cs or (B) HUVECs using ELISA. Results are mean $\pm$ S.E.M. from five experiments. * $P < 0.05$ compared with unstimulated control. ** $P < 0.001$ compared with unstimulated control.

Receptor phosphorylation with immunoblotting

HMVEC-Cs were stimulated with insulin or IGF1 to investigate the phosphorylation of IR and IGF1R (Fig. 2). Cell lysates were IP with antibodies against the β -subunit of the IGF1R or the β -subunit of the IR. When IP with anti-IGF1R we could detect phosphorylation stimulated by IGF1 10^{-8} mol/l and inconsistently by 10^{-9} mol/l. After IP with anti-IR we found phosphorylation stimulated by IGF1 10^{-8} mol/l and insulin 10^{-8} mol/l, and inconsistently by IGF1 10^{-9} mol/l and insulin 10^{-9} mol/l.

DNA synthesis and glucose accumulation

The effect of IGF1 on thymidine incorporation in HMVEC-Cs appeared at an IGF1 concentration of 10^{-9} mol/l (Fig. 4) and was highly significant at IGF1 10^{-8} mol/l ($P = 0.008$). Insulin also tended to have an effect, appearing at a concentration of 10^{-8} mol/l, but this did not reach statistical significance.

As shown in Fig. 5, the effect of IGF1 on glucose accumulation was more pronounced and tended to appear at

lower concentrations than with insulin. The effect of IGF1 on glucose accumulation was statistically significant at 10^{-7} mol/l ($P = 0.018$). VEGF also stimulated glucose accumulation ($P = 0.003$).

E-selectin expression

No significant effects of insulin 10^{-8} mol/l or IGF1 10^{-8} mol/l on E-selectin expression were found in HMVEC-Cs and HUVECs (Fig. 6A and B). Stimulation with TNF- α 5 ng/ml resulted in a significant increase in E-selectin expression compared with unstimulated control ($P < 0.001$ for both HMVEC-Cs and HUVECs).

The possible suppressant effect of insulin or IGF1 on E-selectin expression was further investigated by stimulating HMVEC-Cs with TNF- α (10, 100, 1000 or 10 000 pg/ml) alone or with TNF- α (10, 100, 1000 or 10 000 pg/ml) and insulin 10^{-8} mol/l or TNF- α and IGF1 10^{-8} mol/l (Fig. 7). We found no significant suppression of E-selectin by insulin or IGF1.

Discussion

To our knowledge this is the first study on IRs and IGF1Rs in HMVEC-Cs. We were able to demonstrate gene and protein expression of both receptors and also evidence of insulin/IGF1 hybrid receptors (Moxham *et al.* 1989). Quantification of receptor phosphorylation, which was possible using a new ELISA, showed activation of IGF1R and of insulin/IGF1 hybrid receptors by IGF1, whereas insulin had little effect even on its cognate receptors. This finding supports our DNA synthesis and glucose metabolism data, again indicating that HMVEC-Cs are sensitive to IGF1 while being insulin resistant.

Figure 4 Thymidine incorporation in HMVEC-Cs. Effects of IGF1 (black bars), insulin (grey bars) and VEGF (white bar) on the incorporation of [3 H]thymidine in HMVEC-Cs. Near confluent cells were stimulated with peptides in serum-free DMEM overnight and then incubated with [3 H]thymidine for 3 h. Results are mean $\pm$ S.E.M. from four separate experiments. * $P < 0.05$ compared with unstimulated control.

Figure 5 Glucose accumulation in HMVEC-Cs. Effects of IGF1 (black bars), insulin (grey bars) and VEGF (white bar) on the accumulation of D-[U- 14 C]glucose in HMVEC-Cs. Near confluent cells were stimulated with peptides and D-[U- 14 C]glucose in serum-free DMEM for 3 h. Results are mean $\pm$ S.E.M. from five separate experiments. * $P < 0.05$ compared with unstimulated control.

Characterisation of cells by quantitative RT-PCR demonstrated that HMVEC-Cs expressed considerably more IGF1R mRNA than IR mRNA. We have previously described this in dermal microvascular cells and in macrovascular endothelial cells (Chisalita & Arnqvist 2004, Nitert *et al.* 2005, Chisalita *et al.* 2006). IGF1R protein could be quantitatively measured by ELISA while IR was below the limit of detection. As the ELISA assay was fivefold less sensitive for IR than for IGF1R, we are cautious in drawing conclusions from these results. If a more sensitive IR ELISA was available we would probably be able to quantify IR too. Ligand binding, a classical method for analysing receptor numbers, has shown less specific binding of insulin than IGF1 to micro- and macrovascular cells (Chisalita & Arnqvist 2004, Nitert *et al.* 2005, Chisalita *et al.* 2006). The evidence available thus suggests that IGF1Rs are more abundant than IRs in HMVEC-Cs. We compared freshly isolated and cultured HUVECs and could find no difference in the gene expression of IGF1R relative to IR. This suggests that the use of cultured cells is a suitable model for studying the effects of insulin or IGF1 on vascular cells.

When immunoprecipitating our samples with antibodies specific for the IGF1R β -subunit we could detect both the IGF1R β -subunit and the IR β -subunit on the gel, and after IP with antibodies specific for the IR β -subunit we could detect both the IR β -subunit and the IGF1R β -subunit. This can be explained by the assembly of the IR and IGF1R $\alpha\beta$ -dimers resulting in the formation of an insulin/IGF1 hybrid receptor with one $\alpha\beta$ -dimer from each receptor (Moxham *et al.* 1989). Hybrid receptors have been shown to have a binding affinity similar to that of the IGF1R, i.e. binding IGF1, but not insulin, with high affinity (Soos *et al.* 1993, Slaaby *et al.* 2006).

As insulin and IGF1 can cross react with each other's receptors (Siddle *et al.* 2001, Werner *et al.* 2008), we studied specific receptor phosphorylation to see which receptors were activated by IGF1 and insulin. Receptor phosphorylation was

measured using conventional western blot after IP and also with phospho-specific ELISAs, making it possible to quantitate receptor phosphorylation. As expected the IGF1R was stimulated by IGF1 but not by insulin at concentrations $\leq 10^{-8}$ mol/l. A paradoxical observation was that the IR was significantly stimulated by IGF1 but not by insulin when using phospho-ELISA. As the IR was also found to be phosphorylated by IGF1 using western blot, we interpret this observation as an effect of insulin/IGF1 hybrid receptors where IGF1 binding to the IGF1R $\alpha\beta$ -dimer transphosphorylates the IR β -subunit (Ward *et al.* 2007). This corroborates with the findings of Abbas *et al.* (2011) who showed that reduction in the expression of IGF1R by siRNA, thus reducing the number of insulin/IGF1 hybrid receptors, increased the response to insulin in HUVECs.

The effects of both insulin and IGF1 on glucose accumulation in HMVEC-Cs were enhanced at increasing concentrations, with the effect of IGF1 being more pronounced than that of insulin. This finding indicates that HMVEC-Cs, like dermal microvascular cells, are more sensitive to IGF1 than to insulin (Chisalita & Arnqvist

Figure 6 E-selectin expression in HMVEC-Cs and HUVECs. The expression of E-selectin was measured in (A) HMVEC-Cs ($n = 5$) or (B) HUVECs ($n = 4$) after 4 h stimulation with different conditions. ** $P < 0.001$ compared with glucose 5.6 mM.

Figure 7 Effects of insulin and IGF1 on TNF- α -induced E-selectin expression in HMVEC-Cs. E-selectin expression was measured after stimulation with TNF- α alone (white bars), TNF- α and insulin 10^{-8} mol/l (grey bars) or TNF- α and IGF1 10^{-8} mol/l (black bars). Results are mean $\pm$ S.E.M. from three separate experiments.

2004). It should be noted that the insulin-sensitive glucose transporter, GLUT4, which accounts for glucose uptake in skeletal muscle and fat (Leto & Saltiel 2012), was not expressed in these cells. In support of our glucose metabolism data, the cells were more responsive to IGF1 with regards to mitogenic effects. The common concept is that insulin stimulates metabolism and IGF1 growth (Dupont & LeRoith 2001, Siddle *et al.* 2001). Our data from phospho-ELISAs, as discussed above, indicate that receptor activation of IGF1R and hybrid receptors only occurred with IGF1 and that insulin had no significant effect even on its cognate receptor. This could explain why we observed no significant effects of insulin while IGF1 had both metabolic and mitogenic effects. In humans the concentration of free circulating bioactive IGF1 is 10^{-10} to 10^{-9} mol/l while the highest postprandial insulin concentrations reached are around 10^{-9} mol/l (Carey *et al.* 2003, Frystyk 2004). In diabetes, particularly in type 1 diabetes, circulating IGF1 bioactivity is low, probably due to insulin deficiency in the portal vein (Bereket *et al.* 1999). One may speculate that this may be of special importance for IGF-sensitive cells as HMVEC-Cs leading, amongst other things, to impaired NO production (Tsukahara *et al.* 1994).

The role of inflammation in vascular disease has been in focus in recent years. We found that TNF- α had a pronounced pro-inflammatory effect in HMVEC-Cs and also in HUVECs, whereas high glucose, insulin, IGF1 or IL6 did not affect E-selectin expression. Prominent effects of TNF- α on E-selectin expression have previously been shown in HUVECs and in human aortic endothelial cells (Strindhall *et al.* 1997, Ewart *et al.* 2008, Mako *et al.* 2010). The lack of insulin or IGF1 effects is in agreement with observations made with HUVECs (Balaram *et al.* 1997, Montagnani *et al.* 2002, Madonna *et al.* 2004). High glucose concentrations (20 mmol/l or higher) was found to increase E-selectin expression in HUVECs after incubation for 24 h or longer (Zheng *et al.* 2008, Wang *et al.* 2010). We incubated our cells in high concentration glucose for 4 h, which could explain

the absence of a glucose effect. In future studies it is therefore of interest to study the effect of high glucose concentration on E-selectin expression in HMVEC-Cs under prolonged incubation; this is especially interesting as hyperglycaemia in diabetes seems to be particularly harmful for the micro-circulation (UKPDS 1998). Stimulation of HMVEC-Cs with TNF- α showed a dose-related E-selectin expression similar to previous results with HUVECs (Mako *et al.* 2010). The lack of anti-inflammatory effects of insulin and IGF1 might be explained by the more potent pro-inflammatory effects of TNF- α .

In conclusion, we show that HMVEC-Cs express more IGF1Rs than IRs and at physiological concentrations of insulin and IGF1, HMVEC-Cs mainly react to IGF1 probably due to the predominance of IGF1Rs and insulin/IGF1 hybrid receptors. TNF- α has a pronounced pro-inflammatory effect on HMVEC-Cs, which is not counteracted by insulin or IGF1.

Declaration of interest

The authors declare that there is no conflict of interests that should be perceived as prejudicing the impartiality of the research reported.

Funding

Financial support was obtained from the County Council of Östergötland, the Barndiabetesfonden and the Lions foundation.

Acknowledgements

The authors thank Anna-Kristina Granath for excellent technical assistance.
