Abstract

The cause of type 1 diabetes continues to be a focus of investigation. Studies have revealed that interferon α (IFN α) in pancreatic islets after viral infection or treatment with double-stranded RNA (dsRNA), a mimic of viral infection, is associated with the onset of type 1 diabetes. However, how IFN α contributes to the onset of type 1 diabetes is obscure. In this study, we found that 2-5A-dependent RNase L (RNase L), an IFN α -inducible enzyme that functions in the antiviral and antiproliferative activities of IFN, played an important role in dsRNA-induced onset of type 1 diabetes. Using RNase L-deficient, rat insulin promoter-B7.1 transgenic mice, which are more vulnerable to harmful environmental factors such as viral infection, we demonstrated that deficiency of RNase L in mice resulted in a significant delay of diabetes onset induced by polyinosinic:polycytidylic acid (poly I:C), a type of synthetic dsRNA, and streptozotocin, a drug which can artificially induce type 1-like diabetes in experimental animals. Immunohistochemical staining results indicated that the population of infiltrated CD8⁺ T cells was remarkably reduced in the islets of RNase L-deficient mice, indicating that RNase L may contribute to type 1 diabetes onset through regulating immune responses. Furthermore, RNase L was responsible for the expression of certain proinflammatory genes in the pancreas under induced conditions. Our findings provide new insights into the molecular mechanism underlying β -cell destruction and may indicate novel therapeutic strategies for treatment and prevention of the disease based on the selective regulation and inhibition of RNase L.

Introduction

The etiology of diabetes continues to be a focus of investigation. Both genetic and environmental factors such as toxins, viruses, and diets are believed to play

an important role in its pathogenesis (Mathis *et al.* 2001). A reduction in insulin-producing pancreatic β -cells has been considered to be one of the key factors in the

development of diabetes, particularly type 1 diabetes (Yoon & Jun 2001, Mandrup-Poulsen 2003). In type 1 diabetes, autoimmune destruction of the pancreatic β -cells results in an absolute loss of insulin production. Investigation of the molecular mechanisms underlying β -cell destruction has revealed that microbial infection recruits immune effectors mediating β -cell apoptosis, which in turn triggers autoimmune responses (Anderson & Bluestone 2005). NOD mice are an ideal model of spontaneous type 1 diabetes, a T-cell-mediated autoimmune disease. Results from histological studies have indicated that infiltration of immune cells, including macrophages and lymphocytes, around the islets in NOD mice starts at 3–4 weeks of age, causing insulinitis (Solomon & Sarvetnick 2004, Anderson & Bluestone 2005). It has been well demonstrated that $CD4^+$ and $CD8^+$ T cells play an important role in the onset of type 1 diabetes. Results from clinical and animal studies have demonstrated that $CD8^+$ T cells take a central stage in the destruction of pancreatic β -cells and contribute to sustaining islet inflammation, leading to the onset of type 1 diabetes (Solomon & Sarvetnick 2004, Anderson & Bluestone 2005, Coppieters & von Herrath 2011, Coppieters *et al.* 2012).

The expression of proinflammatory genes has been implicated in the pathogenesis of type 1 diabetes (Bergholdt *et al.* 2004). In NOD mice, increased expression of $IFN\gamma$, $TNF\alpha$, and $IL1\beta$ is associated with β -cell-destructive insulinitis (Solomon & Sarvetnick 2004, Anderson & Bluestone 2005). In recent years, the role of $IFN\alpha$ in autoimmune diseases including type 1 diabetes has been well established (Selmi *et al.* 2006). Increased levels of $IFN\alpha$ in the sera of type 1 diabetic patients have been documented (Chehadeh *et al.* 2000). Transgenic mice expressing $IFN\alpha$ (IFNA) in the β -cells develop hypoinsulinemic diabetes associated with a mixed inflammation centered on the islet, which can be prevented with a neutralizing antibody to $IFN\alpha$ (Stewart *et al.* 1993). It has been reported that the onset of type 1 diabetes in both BB rats and streptozotocin (STZ)-treated mice is $IFN\alpha$ -dependent (Huang *et al.* 1994). In addition, $IFN\alpha$ mediates induction of type 1 diabetes by poly I:C in mice expressing the B7.1 costimulatory molecule driven by the rat insulin promoter (RIP) on β -cells in islets (Devendra *et al.* 2005). Most recently, a study has revealed that blockade of $IFN\alpha$ signaling by anti- $IFNAR1$ in 2- to 3-week-old NOD mice remarkably delays the onset and decreases the incidence of diabetes, indicating the involvement of IFN -stimulated genes in the pathogenesis of type 1 diabetes (Li *et al.* 2008).

RNase L is an IFN -inducible enzyme and plays an important role in the 2-5A system of IFN action against viral infection and cellular proliferation (Silverman 1996).

The 2-5A system consists of two enzymes: 2-5A synthetase and RNase L. $IFNs$ induce a family of 2-5A synthetase genes. The 2-5A synthetases require double-stranded RNA (dsRNA) for their activities. dsRNA is frequently produced during viral infection. After activation by dsRNA, 2-5A synthetases convert ATP molecules to pyrophosphate (ppi) and a series of unique, 5'-phosphorylated, 2'-5' linked oligoadenylates known as 2-5A with the general formula $ppp(A2'p5')_nA$ ($n \geq 2$). 2-5A binds RNase L with a high affinity, converting it from its inactive, monomeric state to a potent dimeric endoribonuclease, resulting in degradation of single-stranded viral and cellular RNAs (Zhou *et al.* 1993). It has been demonstrated that 2-5A accumulates and RNase L is activated in infected cells. Cells overexpressing RNase L overcome viral infection (Zhou, *et al.* 1998). In contrast, overexpression of a dominant negative mutant of RNase L results in increased susceptibility to certain viruses (Hassel *et al.* 1993). Results from *in vivo* studies indicated that mice containing targeted disruption of RNase L gene succumb to encephalomyocarditis (EMCV) infection more rapidly than infected WT mice (Zhou *et al.* 1997). Interestingly, 2-5A synthetase is persistently activated in patients with type 1 diabetes, indicating its involvement in this disease (Bonnievie-Nielsen *et al.* 2000). RNase L-null mice show enlarged thymus glands and increased T cell numbers at an early age, indicating that RNase L may be involved in T cell development, which probably results from reduced cell apoptosis. Furthermore, it has been demonstrated that overexpression of RNase L in the cells enhances cell apoptosis, whereas dominant negative RNase L suppresses cell apoptosis (Zhou *et al.* 1997). These observations indicate that RNase L plays an important role in the immune system. Indeed, studies have revealed that skin allograft rejection is suppressed in mice lacking RNase L, indicating the involvement of RNase L in T cell immunity, particularly $CD4^+$ T cell-mediated immunity (Silverman *et al.* 2002). In addition, alphavirus-based DNA vaccination against a non-mutated tumor-associated self-antigen (tyrosinase-related protein-1, TRP-1) is severely impaired in RNase L-null mice, indicating that RNase L plays an important role in the host's immune response against cancer (Leitner *et al.* 2003).

In this study, we present evidence indicating that RNase L may be involved in the pathogenesis of type 1 diabetes. RNase L-deficient RIP-B7.1 mice displayed significantly delayed onset of diabetes induced by STZ and poly I:C. Immunohistostaining revealed that the population of infiltrated $CD8^+$ T cells was remarkably reduced in the islets of RNase L-deficient mice, implicating RNase L in the onset of type 1 diabetes through mediating

the infiltration of immune cells. Furthermore, RNase L regulated the expression of certain proinflammatory genes in the pancreas under these conditions. Our results are indicative of a novel role of RNase L in the development of type 1 diabetes.

Reagents and methods

Tissue culture and animal treatment

NIH 3T3 cells, NIT-1 (ATCC, Manassas, VA, USA), and mouse embryonic fibroblasts (MEFs) were grown in DMEM (Cleveland Clinic, Cleveland, OH, USA) supplemented with 10% fetal bovine serum (PAA Laboratories, Dartmouth, MA, USA) and antibiotics in a humidified atmosphere of 5% CO₂ at 37 °C. BMMs were generated from the bone marrow cells of RNase L-deficient and WT C57BL/6 mice using a modified method (Yi *et al.* 2013). For RNase L induction in the pancreas of mice, each group ($n=2$) of C57BL/6 mice were treated with or without poly I:C at a concentration of 5 µg/g body weight every other days for 1 week (three times). The pancreases were removed and tissue extracts were used for analysis of RNase L. For treatment with a high-fat diet, RNase L^{+/+} and RNase L^{-/-} mice were fed a high-fat diet (21% milk fat, 1.25% cholesterol, and 0.5% sodium cholate) (Harlan Teklad, Madison, WI, USA) for 20 weeks. The body weight was monitored every 2 weeks and the blood from the eye corner was collected for analysis of glucose, cholesterol, triglyceride, and insulin. This study was carried out in strict accordance with the recommendations in the Guide for the Care and Use of Laboratory Animals of the National Institutes of Health. The protocol was approved by the Committee on the Ethics of Animal Experiments of Cleveland State University (Permit Number: 21111-ZHO-AS). All efforts were made to reduce suffering. Mice were anaesthetized under CO₂ for 5 min and then their necks were dislocated at the end of the experiments.

Generation of an RNase L-deficient C57BL/6.RIP-B7.1 mouse

An RNase L^{-/-} mouse (C57BL/6) (a generous gift from Dr Robert Silverman, Cleveland Clinic) was cross-bred with a C57BL/6.RIP-B7.1 mouse (Barbara Davis Center of Childhood Diabetes, University of Colorado Health Sciences Center, Denver, CO, USA). Genotyping for RNase L and B7.1 was performed by PCR under the following conditions: denaturation at 96 °C for 4 min, for each cycle, denaturation at 96 °C for 45 s, annealing at 55 °C for 45 s, and extension at 72 °C for 1.5 min, for

32 cycles, then an additional cycle at 72 °C for 5 min. The primers used were as follows: RNase L, 5'-GCA TTG AGG ACC ATG GAG AC-3' and 5'-GGA GGA GAA GCT TTA CAA GGT-3' and, B7.1, 5'-TGA AGC CAT GGG CCA CAC-3' and 5'-GGC TCC TTG TCG GCG TTC TA-3'.

Diabetes induction

Six-week-old RNase L-deficient and WT C57BL/6 RIP-B7.1 mice received i.p. injections of with poly I:C (Sigma) daily at a concentration of 5 µg/g body weight for 7 days, and then immunized (i.p.) with 25 µg/mouse insulin (Eli Lilly, Indianapolis, IN, USA) on day 14 after poly I:C treatment. Blood glucose was measured weekly using a Glucose Oxidase Reagent Set (Pointe Scientific, Canton, MI, USA). Briefly, 10 µl of plasma was mixed with 1 ml of the working reagent provided by the manufacturer and incubated at 37 °C for exactly 5 min. After incubation, the absorbance at 500 nm was read and recorded. Mice were considered diabetic after two consecutive blood glucose values of at least 250 mg/dl.

Immunohistostaining

The pancreases obtained from mice were fixed in 10% formalin, paraffin embedded, sectioned at a thickness of 5 µm, and subsequently stained with hematoxylin and eosin. Pancreatic sections were microscopically examined for infiltration of immune cells. The tissue sections were incubated with rat polyclonal antibodies against CD4, CD8, F4/80, and CD11b (eBioscience, San Diego, CA, USA) respectively and a MAB to insulin (Abcam, Cambridge, MA, USA), followed by incubation with a biotinylated secondary antibody, and color reaction was obtained by sequential incubation with avidin-peroxidase conjugate and diaminobenzidine-hydrogen peroxide (ICN, Costa Mesa, CA, USA).

Flow cytometry

Single-cell suspensions from the spleens were stained with conjugated mAbs including FITC-CD4, PE-CD8, FITC-IgD, PE-B220, and PE-cy7-CD25 (BD Pharmingen, San Jose, CA, USA). Cell-associated fluorescence was analyzed with a FACScan instrument and the associated Winlist 5 software.

Western blot analysis

After treatment, cells were washed twice with ice-cold PBS and collected with a scraper. Western blot analysis

was performed as described by Mandrup-Poulsen (2003). Pancreatic tissue extracts obtained from mice (two per group) treated with or without poly I:C (Sigma) every other day at a concentration of 5 µg/g body weight for 1 week (three times) were analyzed as described earlier.

ELISA

The levels of expression of proinflammatory genes in the extracts of the pancreases were measured by ELISA using commercial available kits (eBioscience and R&D Systems, Minneapolis, MN, USA) according to the manufacturer's instructions. Plates were read at an absorbance of 450 nm in a 96-well LD 400C microplate reader (Beckman Coulter, Fullerton, CA, USA).

Results

Minimal impact of RNase L on high-fat-diet-induced obesity

It has been previously observed that RNase L^{-/-} mice gained significantly more body weight than RNase L^{+/+} mice and displayed hepatic steatosis and lipid droplets within renal tubular epithelial cell cytoplasm during their old age (Fabre *et al.* 2012). To determine whether RNase L plays any role in the metabolic pathways, we fed RNase L^{+/+} and RNase L^{-/-} mice a high-fat diet for 20 weeks. Surprisingly, the growth rate of both mouse types was almost identical under the same conditions (Fig. 1A). However, the levels of glucose, cholesterol, and triglyceride were 20.4, 11.6, and 2.5%, respectively, higher in the serum from RNase L^{-/-} mice compared with that from RNase L^{+/+} mice (Fig. 1B, C, and D), although the level of insulin was also 18.7% higher (E) in the serum from RNase L^{-/-} mice. These results indicate that RNase L may not be involved directly in the increase in body weight, but contribute, at least in part, to the metabolic pathways.

IFNα and poly I:C induce the expression of RNase L in the tissues and cells

RNase L is one of the key enzymes involved in the IFN-induced antiviral and antiproliferative functions. RNase L is also found to be expressed in almost all types of mammalian cells from mouse to human (Silverman 1996). To examine the expression of RNase L in the pancreas, the tissue extracts of eight different organs from a C57BL/6 mouse (Jackson Laboratory, Bar Harbor, ME, USA) were analyzed by the 2-5A binding assay (Nolan-Sorden *et al.* 1990). As shown

Figure 1

Effect of RNase L on diet-induced obesity. RNase L^{+/+} and RNase L^{-/-} male mice ($n=8$ /group) were fed a high-fat diet (Harlan Teklad) for 20 weeks. The body weight was measured every 2 weeks (A). Glucose (B), cholesterol (C), and triacylglycerol (D) in the plasma were analyzed using commercially available diagnostic kits from Sigma-Aldrich, and insulin (E) was measured using an ELISA kit (Fisher, Hanover, IL, USA). Data are expressed as mean $\pm$ s.d. for eight mice of each strain. The samples were run in triplicate in every assay and two individual experiments were performed, * $P<0.05$, ** $P<0.01$.

in Fig. 2A, RNase L is clearly expressed in the tissues. High levels of the RNase L expression were found in the lung, spleen, and thymus. However, the basal level of RNase L in the pancreas was very low. Similar to our previous observation, RNase L was found to be highly expressed in primary immune cells (Fig. 2B), indicating a possible role of RNase L in the immune system. To determine whether IFNα is able to induce the expression of RNase L in the pancreatic cells, NIT cells, a murine β-cell line, were treated with or without IFNα and the induction of RNase L was examined by western blot analysis. The expression of RNase L was highly induced in β-cells (Fig. 2C). dsRNA such as poly I:C can be used to mimic viral infection *in vitro* and *in vivo*. To examine whether poly I:C is able to upregulate the RNase L expression in the pancreas, mice were treated with or without poly I:C and the expression of RNase L

Figure 2

Tissue distribution and expression of RNase L. The expression of RNase L in the tissue extracts from eight organs (A) and several types of cells (B). Sp-cells, primary splenocytes; BMM, bone marrow-derived macrophages; NIH3T3, mouse fibroblasts; MEFs, mouse embryonic fibroblasts. (C) IFN α induces the expression of RNase L in NIT-1 cells. NIT-1 cells were treated with 1000 units/ml of IFN α (R&D Systems) for 16 h and the level of RNase L in the cells was determined by western blot analysis. (D) Mice (two per group) were treated with or without poly I:C at a concentration of 5 μ g/g body weight every other days for 1 week (three times) and the level of RNase L in the pancreatic tissue extracts was determined by western blot analysis with a polyclonal antibody to mouse RNase L.

in the pancreatic tissue extracts was measured. Poly I:C was a potent inducer of the RNase L expression in the pancreas (Fig. 2D).

The onset of type 1 diabetes is delayed in RNase-L-deficient mice

Viral infection is believed to be a potent factor in triggering autoimmune responses in the pancreas, resulting in destruction of β -cells, leading to absolute deficiency of insulin. Indeed, poly I:C, a type of dsRNA commonly used to mimic viral infection, is able to effectively induce the onset of type 1 diabetes in C57BL/6 mice expressing B7.1 under the control of a RIP on pancreatic β -cells islets (RIP-B7.1) in an IFN α -dependent manner (Devendra *et al.* 2005). RNase L can be induced by both poly I:C and IFN α *in vitro* and *in vivo*

and mediates the functions of IFN α . To determine the role of RNase L in the onset of type 1 diabetes induced by poly I:C, RNase L^{-/-} RIP-B7.1 mice were created by cross-breeding an RNase L^{-/-} mouse (C57BL/6) with a C57BL/6.RIP-B7.1 mouse (RIP-B7.1 mouse). The genotype of these mice was determined by PCR as shown in Fig. 3A. The onset of type 1 diabetes was first induced using STZ, a glucose analog known to induce diabetes in experimental animals. Mice received i.p. injections of 40 mg/kg STZ for five consecutive days, the blood was collected from the saphenous vein, and the level of glucose was measured as described in the Reagents and methods section. As shown in Fig. 3B, mice with RIP-B7.1 were more sensitive to STZ-induced onset of diabetes and RNase L deficiency markedly delayed the progress of this disease. To determine whether RNase L mediates poly I:C-induced onset of type 1 diabetes, RNase L^{+/+} and RNase L^{-/-} RIP-B7.1 mice received injections (i.p.) of 5 μ g/g body weight poly I:C daily for 7 days, and then injections (i.p.) of insulin at a dose of 25 μ g/mouse on day 14 after poly I:C treatment. Diabetic progress in these mice was monitored every week and mice were considered diabetic after observation of two consecutive blood glucose values of at least 250 mg/dl. As shown in Fig. 3C, the onset of diabetes was significantly delayed in the RNase L^{-/-} RIP-B7.1 mice.

Figure 3

Effect of RNase L on STZ- and poly I:C-induced diabetes. (A) Genotyping of B7.1-RL^{-/-} mice. (B) Incidence of diabetes in RNase L (RL)^{+/+} and RL^{-/-} ($n=10$ for each group), B7.1-RL^{+/+} ($n=8$) and B7.1-RL^{-/-} ($n=9$) mice after injection of 40 mg/kg STZ for five consecutive days. (C) Incidence of diabetes in B7.1-RL^{+/+} ($n=9$) and B7.1-RL^{-/-} ($n=8$) mice after injection of 5 μ g/g body weight poly I:C intraperitoneally daily for 7 days, and then injection of 25 μ g/mouse of insulin intraperitoneally on day 14 after poly I:C treatment. The glucose levels in the blood samples were measured using a blood sugar test kit (Pointe Scientific). Mice were considered diabetic after measurement of two consecutive blood glucose values of at least 250 mg/dl.

RNase L facilitates infiltration of immune cells

RNase L is highly expressed in the thymus, spleen, and all immune cells examined. As the infiltration of immune cells initiates the progress of this disease, we investigated whether the delay in the onset of type 1 diabetes was caused by slowdown of immune responses in the pancreases of RNase L-deficient mice. RNase L^{+/+} and RNase L^{-/-} RIP-B7.1 mice were treated with poly I:C for 40 days and then killed and the pancreatic tissues were embedded and sectioned at a thickness of 5 µm, followed by hematoxylin and eosin (H&E) staining. Interestingly, the population of infiltrated immune cells was strikingly reduced in the islets of RNase L^{-/-} mice, indicating that the involvement of RNase L in poly I:C-induced onset of diabetes may be through the regulation of the infiltration of immune cells (Fig. 4A). To determine the identity of these infiltrated immune cells, immunohistostaining for macrophages, CD4⁺, and CD8⁺T cells was performed. Apparently, the majority of the infiltrated immune cells in the islets of the pancreas from RNase L^{+/+} mice were CD8-positive T cells, although some CD4-positive T cells were found in islets from both types of mice (Fig. 4B). However, macrophages were undetectable in the islets from both types of mice using either CD11b or F4/80 as a biomarker (not shown). The finding indicates that CD8-positive T cells may be the effector cells in the destruction of β-cells in the islets of the pancreas from RNase L^{+/+} RIP-B7.1 mice after poly I:C treatment. As expected, the insulin levels in the islets of RNase L^{-/-} mice were significantly higher than those in RNase L^{+/+} mice before and after poly I:C treatment (Fig. 4C).

RNase L is associated with subclasses of immune cells in the spleen and T cell function in the blood

RNase L^{-/-} mice display enlarged, hypercellular thymuses, indicating that RNase L may be involved in the development of thymocytes and T cell function. To determine whether RNase L affects T cell function, lymphocytes isolated from the blood of RNase L^{+/+} and RNase L^{-/-} mice were subjected to analysis of their cytotoxic activity against retinal endothelial cells. As shown in Fig. 5A, lymphocytes from RNase L^{-/-} mice exerted 46% lower cytotoxic activity than those from RNase L^{+/+} mice. CD4⁺CD25⁺ regulatory T cells (Tregs) have emerged as a dominant peripheral mechanism of immune suppression of self-reactive T cells and a master switch factor controlling the balance between tolerance and immunity (Johnson *et al.* 2013). It has

Figure 4

RNase-L-dependent infiltration of immune cells in the islets in response to poly I:C. (A) Hematoxylin and eosin-stained pancreatic islets from B7.1-RL^{+/+} and B7.1-RL^{-/-} mice after treatment with or without poly I:C. (B) Immunohistological staining of CD4⁺ and CD8⁺ T cells in the islets from the two types of mice after poly I:C treatment. (C) Immunohistological staining of insulin in the islets from the two types of mice before and after poly I:C treatment. Magnification ×40.

been demonstrated that CD4⁺CD25⁺ Tregs, in particular CD4⁺CD25⁺FoxP3⁺ Tregs, are very important in controlling the development of diabetes in NOD mice (Manirarora *et al.* 2008, Kaminitz *et al.* 2014).

Figure 5

Effect of RNase L on splenic immune cell subtypes and T cell function. (A) Lymphocytes isolated from RNase L^{+/+} and RNase L^{-/-} mice ($n=4$ /group) were incubated with retinal endothelial cells at 1:5 at 37 °C for 24 h. Cell viability was measured by trypan blue exclusion. Samples were run in triplicate and the data are expressed as mean $\pm$ s.d., *** $P<0.048$. (B and C) Tregs in the spleens of RNase L^{+/+} (WT) and RNase L^{-/-} (KO) mice were analyzed for the expression of CD4 and CD25 by flow cytometric analysis. The percentages of

CD4⁺CD25⁺ Tregs and CD4⁺CD25⁺Foxp3⁺ Treg cells in total CD4⁺T cells are expressed as mean $\pm$ s.d. ($n=4$). * $P<0.05$; ** $P<0.025$. (D and E) Six-week-old male RNase L^{+/+} and RNase L^{-/-} mice (three mice per group) were treated with or without 25 μ g LPS for each mouse every other day for a week. The splenic cells were subjected to cell sorting after labeling with CD4, CD8, B220, and IgD alone or in combination. A full colour version of this figure is available via <http://dx.doi.org/10.1530/JOE-14-0509>.

To determine the effect of RNase L on CD4⁺CD25⁺ Tregs, we performed a flow cytometric assay to analyze the subtype of these cells in the spleen of RNase L^{+/+} and RNase L^{-/-} mice. Interestingly, the percentage of CD4⁺CD25⁺ Tregs in CD4⁺T cells in the spleens of RNase L^{-/-} mice was significantly higher than that in those of RNase L^{+/+} mice. In particular the percentage of CD4⁺CD25⁺foxP3⁺ Tregs in CD4⁺T cells was 13.3% in the spleens of RNase L^{-/-} mice when compared with 5.2% in the spleens of RNase L^{+/+} mice (Fig. 5B and C). The population of other cell subclasses was also differentially represented in the spleens of RNase L^{+/+} and RNase L^{-/-} mice, especially under stimulation with LPS as shown in Fig. 5D and E. The population of CD4⁺CD8⁺T cells in the spleens of RNase L^{-/-} mice was 37% less than that in the spleens of RNase L^{+/+} mice, whereas the population of the double-labeled T cells was 72% less in the spleens of RNase L^{-/-} mice when compared with that in the spleens of RNase L^{+/+} mice after treatment with LPS. Similar to CD4⁺CD8⁺T cells, the population of B220⁺IgD⁺B cells in the spleens of RNase L^{-/-} mice was 39% less than that in the spleens of RNase L^{+/+} mice after LPS stimulation, although the population of B220⁺IgD⁺B cells in the spleens of intact RNase L^{-/-} mice was slightly higher than that in the spleens of RNase L^{+/+} mice under the same conditions. Taken together, the results implicate RNase L in immune system activities through mediating the context-specific modulation of immune cell subclasses in the spleen.

The expression of proinflammatory cytokines in the pancreatic tissues

In addition to IFN α , several proinflammatory genes such as TNF α , IL1 β , and IFN γ are believed to contribute to the development of type 1 diabetes (Solomon & Sarvetnick 2004, Anderson & Bluestone 2005). To determine whether deficiency of RNase L affects the expression of TNF α , IL1 β , IL6, and IFN γ , RNase L^{+/+} and RNase L^{-/-} RIP-B7.1 mice were treated with poly I:C at a concentration of 5 μ g/g body weight every other day for a week and the level of these gene products in the pancreatic extracts was determined by ELISA. As shown in Fig. 6, RNase L deficiency reduced IFN γ and TNF α production by 37.5 and 48.5%, respectively, in the pancreas after treatment with poly I:C. However, the expression of IL1 β and IL6 was found to be slightly higher in the pancreases from RNase L^{+/+} mice when compared with the pancreases from RNase L^{-/-} mice.

Figure 6

RNase L regulates the expression of proinflammatory genes. RNase L-deficient and WT RIP-B7.1 mice were treated with poly I:C at a concentration of 5 μ g/g body weight every other day for a week and the level of these factors in the pancreatic extracts was determined by ELISA using an ELISA kit for each of the analyzers. Experiments were carried out two times in triplicates. Data are expressed as mean $\pm$ s.d., $P < 0.01$.

Discussion

B7.1 and B7.2 are homologous costimulatory ligands expressed on the surface of antigen-presenting cells (APCs). Binding of these molecules to the T cell costimulatory receptors, CD28 and CTLA-4, is essential for the activation and regulation of T cell immunity (Greenwald *et al.* 2005). Although expression of the B7.1 costimulator alone is not sufficient to induce diabetes in mice, β -cells expressing the molecule are more vulnerable to harmful environmental factors such as viral infection, resulting in the destruction of β -cells and leading to disease (Wong *et al.* 1995). As a mimic of viral infection, poly I:C treatment alone can induce insulinitis, but cannot lead to diabetes in C57BL/6 mice. However, it can effectively induce diabetes in C57BL/6 mice expressing B7.1 on β -cells in the islets under the control of a RIP (Devendra *et al.* 2005). In this study, we present evidence indicating that RNase L^{-/-} RIP-B7.1 mice display a significant delay of type 1 diabetes onset induced by poly I:C, indicating that RNase L is associated with the pathogenesis of this disease.

The role of RNase L in mediating IFN-induced actions against viral infection and cell proliferation has been well established. A line of evidence has shown that IFN α plays a vital role in initiating autoimmune responses and the molecular mechanism is a continuing subject of investigation. Studies have revealed that the onset of type 1 diabetes in animal models induced by STZ and poly I:C is IFN α -dependent (Huang *et al.* 1994, Devendra *et al.* 2005). In humans, the development of type 1 diabetes has been widely documented during IFN α therapy for viral infections

such as hepatitis B and C (di Cesare *et al.* 1996, Kose *et al.* 2012). How IFN α promotes the onset of type 1 diabetes remains to be further elucidated. RNase L is one of the key enzymes in the 2-5A system of IFN α function. 2-5A activation of RNase L results in apoptosis in cells. It is believed that apoptosis is one of the key factors in triggering autoimmune responses in islets (Kawazoe *et al.* 2012). Thus, our results indicate that poly I:C treatment may induce an increase in IFN α production in islets and subsequently activate the 2-5A system. Activation of the 2-5A system, in turn, leads to β -cell apoptosis, which further promotes the autoimmune responses resulting in destruction of β -cells and diabetes onset. Deficiency of RNase L in mice delays the onset of type 1 diabetes. Actually, this hypothesis is supported by a previous study in which poly I:C induces cell apoptosis in pancreatic islets, resulting in the release of islet autoantigens, triggering the autoimmune responses. By contrast, none of the bacterial products such as LPS and CpG are able to induce diabetes in these mice because they cannot induce islet cells to undergo overt apoptosis (Maniati *et al.* 2008).

RNase L may be involved directly in the action of immune cells to affect the development of type 1 diabetes. Although T lymphocytes are primarily the effectors, results from previous studies have indicated that B cells may play a vital role in the pathogenesis of autoimmune diseases. In NOD mice, the contribution of B cells was clearly demonstrated by the remarkable reduction in the incidence of insulinitis and diabetes after B cell depletion using anti-IgM antibodies at birth or in NOD mice genetically deficient in B cells (Silveira & Grey 2006, Mariño *et al.* 2011). Using the same animal model, it has been demonstrated that B cells function as islet antigen-presenting cells for autoreactive T cells and produce antibodies that are directly pathogenic. In clinical trials, patients with type 1 diabetes treated with rituximab, a chimeric MAB against the protein CD20 that is primarily found on the surface of B cells, decreased C-peptide and reduced insulin requirements, indicating an essential role of B cells in the development of this disease (Pescovitz *et al.* 2009). Interestingly, the populations of B220⁺IgD⁺ double-labeled B cells and CD4⁺/CD8⁺ double-labeled T cells were 39% and 72% down after LPS treatment (Fig. 2A) or 46% and 45% down after poly I:C treatment (data not shown) in the spleens of RNase L^{-/-} mice, indicating that delayed onset of type 1 diabetes may be due to attenuated immune responses as a result of decreases in the population of certain immune cells, such as B cells, induced by LPS or poly I:C. The effect of RNase L on immunity is a focus of our current investigations.

The production of proinflammatory genes in the islets plays a critical role in the pathogenesis of type 1 diabetes.

It has been demonstrated that disruption of IFN γ function using either IFN γ -specific Abs or soluble IFN γ receptors (IFN γ R) significantly reduces the incidence of spontaneous diabetes in NOD mice, indicating an important role of IFN γ in the development of this disease (Campbell *et al.* 1991, Nicoletti *et al.* 1996). Complete protection from diabetes was observed when *Tnfr1*, but not *Tnfr2* was knocked out in NOD mice although the direct effect of TNFR1 on β -cell death *in vivo* has not been defined clearly (Kägi *et al.* 1999). It has been reported that RNase L mediates the expression of certain genes through regulating RNA turnover (Bisbal *et al.* 2000, Chandrasekaran *et al.* 2004). Our results indicate that RNase L specifically regulating the expression of proinflammatory genes in the pancreas may contribute to the onset of type 1 diabetes induced by poly I:C. Interestingly, RNase L seemed not to influence the growth rate of mice fed a high-fat diet, but the level of blood glucose in RNase L^{-/-} mice was significantly higher although the insulin level was markedly increased, indicating that insulin sensitivity in RNase L^{-/-} cells may be impaired. Indeed, we have observed that phosphorylation of Akt, a key component of the insulin signaling pathway, in RNase L^{-/-} MEFs and primary hepatocytes stimulated by insulin was significantly reduced when compared with that in the same type of RNase L^{+/+} cells (L Zhang and A Zhou unpublished observations). Thus, this study highlights the potential benefits of targeting RNase L in treatment of type 1 diabetes.

Declaration of interest

The authors declare that there is no conflict of interest that could be perceived as prejudicing the impartiality of the research reported.

Funding

This work was supported by Marousch Award, the Diabetes Association of Greater Cleveland to A Z and partially by grants from the National Institutes of Health (R15DK084460-01A2) to A Z and (AI089518) to K M.

Acknowledgements

The authors thank Dr Bret A Hassel (University of Maryland School of Medicine) for helpful comments on the manuscript.
